
Business Requirement Document (BRD)

Project Name: Centralized Exception Handling via One Stop Processing (OSP)

1. Simple Summary & Problem Statement

- **The Problem:**

In daily financial operations, most trade and payment tasks process automatically (known as Straight-Through Processing or STP). However, when an item hits an error or breaks a business rule—such as exceeding a currency payment limit, missing bank account details (SSI), or failing trade validation—it gets stuck. Currently, operators have to check multiple separate screens and technical system queues to fix these issues. Technical queue names are confusing, and there is high operational risk if one person can approve their own flagged transaction.

- **The Solution:**

Implement **One Stop Processing (OSP)**—a single, easy-to-use central dashboard. OSP brings all stuck transactions into one place, translates technical queue names into simple business labels, enforces dual-control (four-eye) safety checks, and groups related tasks so operators can resolve exceptions quickly.

2. End-to-End Workflow Architecture

The diagram below shows how a trade or payment moves through the system, gets caught by an exception, and is manually resolved using OSP:

3. Core Functional Requirements

3.1 Catching Issues in the Workflow

The system catches stopped items using three simple queue types:

1. **Rule Exception Queue (Check Exception):** Automatically holds entries that break business limits (e.g., payment amount too high) and asks the operator to **Accept** or **Reject** the exception.
2. **Hold & Authorization Queue:** Holds payments or trades in a waiting area until another dependent task completes (e.g., holds a payment until the trade confirmation is matched).
3. **System Error Queue:** Catches technical system crashes or broken data so operators can review error logs and fix them.

3.2 Dual-Control Safety (Four-Eye Principle)

To prevent fraud and mistakes:

- **Hide Data:** The system automatically hides a transaction from the user who performed the last check, forcing a second set of eyes to review it.
- **Disable Action Buttons:** Alternatively, the system lets the original user see the transaction but turns off their **Accept** button so only a second user can approve it.
- **Forced Comments:** Operators must type an explanation when rejecting or sending back an item.

3.3 Operator Interface & Usability Improvements

- **Friendly Names:** System technical names (e.g., BO_VAL_TASK_01) are renamed to simple business labels (e.g., Non-Economic Exceptions).
- **Visual Warnings:** Cells or rows automatically turn **RED** if an item contains a severe error code, preventing accidental approvals.
- **Smart Combined Queues:** Operators can view multiple related queues (like pending trades AND pending payments) in a single consolidated screen.
- **Package Auto-Selection:** Selecting one item in a multi-leg transaction (a package) automatically selects all related items so they are processed together.

4. Murex Configuration Screens Used

Configuration Step	Murex Screen Used	Plain Language Purpose
1. Create Queues	Contract / Deliverable Workflow Editor	Adds exception, hold, or error nodes into the business flow.
2. Rename Queues	OSP Queue (OPQ) Configuration	Converts raw system names into easy-to-read business labels.
3. Set User Access & 4-Eye Safety	Supervisor Session > Workflow Management (OSP Right Template & Validation Right Template)	Controls who can view/edit queues and sets up automatic 4-eye data hiding rules.
4. Customize Screen Layout	Config Session > OSP Configuration Templates	Sets visible table columns, filters, red error highlights, and action buttons.
5. Build Combined Views	OSP Configuration Templates	Combines different queues into

Configuration Step	Murex Screen Used	Plain Language Purpose
	> Smart Queues	one unified dashboard view for operators.
6. Daily Operations Dashboard	OSP Navigation Dashboard	The main day-to-day screen used by operations staff to monitor and fix stuck items.
